Reproducible Research - Course Project 2

Pavit Masson

Synopsis

Storms and other severe weather events can cause both public health and economic problems for communities and municipalities. Many severe events can result in fatalities, injuries, and property damage, and preventing such outcomes to the extent possible is a key concern.

This project involves exploring the U.S. National Oceanic and Atmospheric Administration's (NOAA) storm database. This database tracks characteristics of major storms and weather events in the United States, including when and where they occur, as well as estimates of any fatalities, injuries, and property damage.

The basic goal of this assignment is to explore the NOAA Storm Database and answer some questions, such as:

- 1. Across the United States, which types of events (as indicated in the EVTYPE variable) are most harmful with respect to population health?
- 2. Across the United States, which types of events have the greatest economic consequences?

Data Processing

The necessary packages and the data from the storm database used for this analysis were loaded as follows:

```
library(dplyr)

## Warning: package 'dplyr' was built under R version 3.5.2

##
## Attaching package: 'dplyr'

## The following objects are masked from 'package:stats':
##
## filter, lag

## The following objects are masked from 'package:base':
##
## intersect, setdiff, setequal, union

library(ggplot2)
```

Warning: package 'ggplot2' was built under R version 3.5.2

```
url <- "https://d396qusza40orc.cloudfront.net/repdata%2Fdata%2FStormData.csv.bz2"
download.file(url, "StormData.csv")
data <- read.csv("StormData.csv")
data <- tbl_df(data)</pre>
```

For the first question, we will examine the number of fatalities and injuries per event type (EVTYPE).

To get an idea of the data, we'll look at the data in three different ways: by most fatalities (fatal_data), by most injuries (inj data), and by most fatalities plus injuries (q1 data).

```
fatal_data <- data %>% group_by(EVTYPE) %>% summarise(tot_fatal = sum(FATALITIES)) %>% arrange(d
esc(tot_fatal))

inj_data <- data %>% group_by(EVTYPE) %>% summarise(tot_inj = sum(INJURIES)) %>% arrange(desc(to
t_inj))

q1_data <- data %>% group_by(EVTYPE) %>% summarise(total = sum(FATALITIES) + sum(INJURIES)) %>%
arrange(desc(total))
```

For Question 2, the variables we will look at are PROPDMG, PROPDMGEXP, CROPDMG, CROPDMGEXP. According to the guide for the data, we'll use the EXP variables to apply multipliers to PROPDMG and CROPDMG, depending on the values M, B, and K. We'll assume the other values are errors, since they are not mentioned in the guide.

```
q2_data <- data
q2_data$PROPDMGEXP <- toupper(as.character(q2_data$PROPDMGEXP))
q2_data$CROPDMGEXP <- as.character(q2_data$CROPDMGEXP)

# Convert PROPDMGEXP and CROPDMGEXP
q2_data[q2_data$PROPDMGEXP == "K", "PROPDMGEXP"] <- 1000
q2_data[q2_data$PROPDMGEXP == "M", "PROPDMGEXP"] <- 1000000
q2_data[q2_data$PROPDMGEXP == "B", "PROPDMGEXP"] <- 1000000000
q2_data$PROPDMGEXP <- as.numeric(q2_data$PROPDMGEXP)</pre>
```

```
## Warning: NAs introduced by coercion
```

```
q2_data$PROPDMGEXP <- q2_data$PROPDMGEXP %>% replace(., is.na(.), 0)

q2_data[q2_data$CROPDMGEXP %in% c("K","k"), "CROPDMGEXP"] <- 1000
q2_data[q2_data$CROPDMGEXP %in% c("M","m"), "CROPDMGEXP"] <- 10000000
q2_data[q2_data$CROPDMGEXP %in% c("B","b"), "CROPDMGEXP"] <- 10000000000
q2_data$CROPDMGEXP <- as.numeric(q2_data$CROPDMGEXP)</pre>
```

```
## Warning: NAs introduced by coercion
```

```
q2_data$CROPDMGEXP <- q2_data$CROPDMGEXP %>% replace(., is.na(.), 0)

q2_data$PropertyDamage <- as.numeric(q2_data$PROPDMG * q2_data$PROPDMGEXP)
q2_data$CropDamage <- as.numeric(q2_data$CROPDMG * q2_data$CROPDMGEXP)</pre>
```

Similar to question 1, we'll look at the data in three different ways: by most property damage (prop_data), by most crop damage (crop_data), and by the combined total of property and crop damage (q2_data).

```
prop_data <- q2_data %>% group_by(EVTYPE) %>% summarize(TotalPropertyDamage = sum(PropertyDamage))

crop_data <- q2_data %>% group_by(EVTYPE) %>% summarize(TotalCropDamage = sum(CropDamage)) %>% a
rrange(desc(TotalCropDamage))

q2_data <- q2_data %>% group_by(EVTYPE) %>% summarize(Total = sum(PropertyDamage) + sum(CropDamage)) %>% arrange(desc(Total))
```

Results

Question 1

When we look at the data arranged by highest fatalities, we can see Tornado is first by a big margin.

```
fatal_data
```

```
## # A tibble: 985 x 2
##
      EVTYPE
                     tot fatal
##
      <fct>
                          <dbl>
   1 TORNADO
                           5633
##
   2 EXCESSIVE HEAT
##
                           1903
##
   3 FLASH FLOOD
                            978
##
   4 HEAT
                            937
   5 LIGHTNING
##
                            816
   6 TSTM WIND
                            504
##
##
   7 FLOOD
                            470
##
   8 RIP CURRENT
                            368
   9 HIGH WIND
                            248
## 10 AVALANCHE
                            224
## # ... with 975 more rows
```

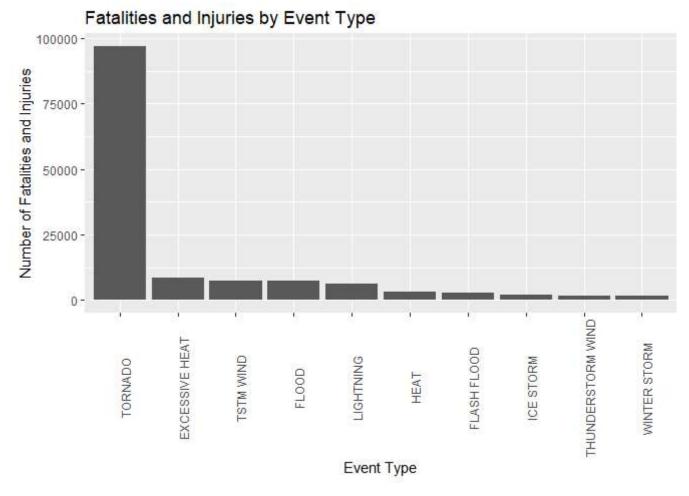

Next, when we see the data arranged by injuries, tornadoes again are first by a big margin.

```
inj_data
```

```
## # A tibble: 985 x 2
      EVTYPE
##
                         tot_inj
##
      <fct>
                            <dbl>
    1 TORNADO
##
                            91346
    2 TSTM WIND
                             6957
##
    3 FLOOD
##
                             6789
    4 EXCESSIVE HEAT
##
                             6525
    5 LIGHTNING
                             5230
##
    6 HEAT
                             2100
##
    7 ICE STORM
##
                             1975
##
    8 FLASH FLOOD
                             1777
    9 THUNDERSTORM WIND
                             1488
## 10 HAIL
                             1361
## # ... with 975 more rows
```

Graph of top 10 events for fatalities plus injuries:

```
g <- ggplot(q1_data[1:10,], aes(reorder(EVTYPE, -total), total)) + geom_bar(stat="identity") +
  theme(axis.text.x = element_text(angle = 90)) + xlab("Event Type") + ylab("Number of Fatalities
  and Injuries") + ggtitle("Fatalities and Injuries by Event Type")
g</pre>
```

From this, we can see that tornadoes cause the most damage with respect to population health; they cause the most fatalities and most injuries.

Question 2

First, let's look at the top 10 events for property damage:

```
prop_data
```

```
## # A tibble: 985 x 2
##
      EVTYPE
                         TotalPropertyDamage
      <fct>
##
                                       <dbl>
##
   1 FLOOD
                               144657709800
##
   2 HURRICANE/TYPHOON
                                69305840000
    3 TORNADO
                                56937160991
##
   4 STORM SURGE
                                43323536000
##
   5 FLASH FLOOD
                                16140812087.
##
                                15732266870
   6 HAIL
##
   7 HURRICANE
##
                                11868319010
   8 TROPICAL STORM
                                 7703890550
   9 WINTER STORM
##
                                 6688497250
## 10 HIGH WIND
                                 5270046260
## # ... with 975 more rows
```

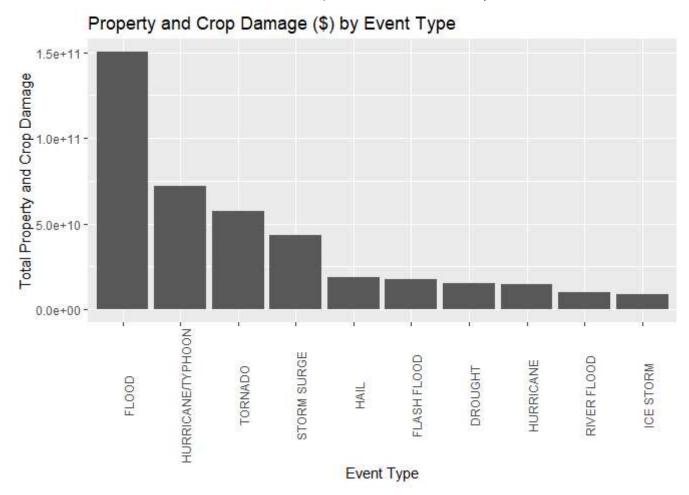

Then, for crop damage:

```
crop_data
```

```
## # A tibble: 985 x 2
      EVTYPE
##
                         TotalCropDamage
      <fct>
##
                                   <dbl>
##
   1 DROUGHT
                             13972566000
##
   2 FLOOD
                              5661968450
   3 RIVER FLOOD
                              5029459000
##
   4 ICE STORM
##
                              5022113500
##
   5 HAIL
                              3025954450
   6 HURRICANE
##
                              2741910000
##
   7 HURRICANE/TYPHOON
                              2607872800
   8 FLASH FLOOD
                              1421317100
##
   9 EXTREME COLD
                              1292973000
## 10 FROST/FREEZE
                              1094086000
## # ... with 975 more rows
```

Finally, we'll graph the top 10 events for the total property plus crop damage:

```
g <- ggplot(q2_data[1:10,], aes(reorder(EVTYPE, -Total), Total)) + geom_bar(stat="identity") +
  theme(axis.text.x = element_text(angle = 90)) + xlab("Event Type") + ylab("Total Property and C
rop Damage") + ggtitle("Property and Crop Damage ($) by Event Type")
g</pre>
```

From this, we can see that floods cause the most economic damage; they cause the most damage for both property and crops, and so also in total.
